AntMover is a automatic text structure analyzer program written in Perl using ActiveState's excellent Komodo 1.2 development environment. The program can be launched by simply double clicking on the self extracting compressed zip file which can be downloaded from the Laurence Anthony laboratory website at <http://antpc1.ice.ous.ac.jp/>. The program can run under any windows environment including Win 98/Me/2000/NT.

If a user finds any problem launching the program under a particular OS, please inform me using the email address below.

Using AntMover is relatively simple, but it has a number of quite advanced features that are accessible through the many menus in the main window. A full user guide is available for viewing online, and is also included in the main AntMover directory. The current version has a single project ready to use. This is a project that analyses the structure of computer science abstracts. The projects can be applied to other fields and text types with varying success.

To use AntMover in its most basic sense, a user must open a text file (or set of text files), which are then imported into the program for analysis. The user can then choose up to four views of the file.

View 1 is the original file without any processing.

View 2 is a processed view of the file, divided automatically into individual sentences

View 3 is a view of the file after a 'moves analysis' has been performed, giving a rhetorical (structural) label automatically to each sentence in the file. This labeling can be used to give the user an idea of the overall structural/rhetorical organization of the text for help when reading or writing in English.

View 4 is an outline view of the structural organization of the file, which the text data itself omitted.

A basic summary of the ideas behind AntMover can be found at http://antpc1.ice.ous.ac.jp/Abs&Sums/cilfe2003/cilfe_abs_2003.htm

A research presentation explaining the theory and development of AntMover can be found at http://antpc1.ice.ous.ac.jp/Abs&Sums/cilfe2003/Cilfe_Pres_2003.files/frame.htm

NOTE: AntMover is still very much in the development stage. In particular, the flow optimization feature requires a special file to be saved in the data sets directory of each project telling the system the probability of common structural steps or moves used in a particular field. In the current implementation of the system, this file is deleted if the system is retrained on a particular project. To keep this file intact, the user should manually remove the file before retraining the system, and then replace it after the retraining has finished.

This problem will be addressed in the next upgrade. Also, when large data sets are used in projects, the system may require a long time to create or retrain a project. During this time, the program may appear to a hang, but this is not the case and a "finished" report will be

displayed when the creation or retraining has completed. In other words, user's should be patient when processing large data sets!

AntMover can be used freely for individual use for non-profit research purposes, and freely distributed on the condition that this readme file is attached in an unaltered state. The software comes on an 'as is' basis, and the author will accept no liability for any damage that may result from using the software. Although there is no support available for AntMover, the author would be happy to hear comments and/or suggestions from anyone using the software, and will try to fix any bugs etc. when time is available.
